Researchers estimate that the human body could contain as many as 75 trillion cells. Each of those cells is surrounded by a bean-shaped membrane made up of dense rows of fatty acids that require protection from lipid peroxidation. Of the many popular antioxidants that help protect cells (e.g., astaxanthin, lutein, lycopene, CoQ10), vitamin E is the one nature chose to reside within the lipid cell membrane to protect its integrity. Vitamin E comes in the perfect molecular shape to do this job—like a tadpole, with a head and tail, similar to the phospholipids that complement the cell membrane. Vitamin E is distinguished by a chromanol head with a lipid-soluble side chain.

There are two forms of vitamin E: tocotrienols and tocopherols. Not all forms of vitamin E are the same, however. Tocopherols have a longer tail (phytyl), whereas tocotrienols have a shorter, more flexible tail (farnesyl). This small difference in molecular structure allows tocotrienols to cover a larger surface area of the cell membrane more quickly, hence making them more effective as antioxidants. As this article will discuss, an expanding body of research points to significant benefits supporting the tocotrienol form.

**Tocotrienols vs. Tocopherols**

When vitamin E was discovered in 1922, it was discovered as alpha-tocopherol. Between that time and 1940, scientists delved into tocopherol research, ranging from alpha-tocopherol's isolation from plants, chemical identification, complete synthesis, and antioxidant activity. In fact, the tocopherol form remained the main focus of vitamin E science for decades, and, as such, research on tocopherols boomed.

Tocotrienols were discovered later, in the mid-1960s. Tocotrienols' ability to lower lipids was first reported in the early 1980s; in the 1990s, tocotrienols were associated with reduction of cardiovascular diseases and inhibition of cancers. Despite the growing research on tocotrienols, they are still often confused with tocopherols and were not even properly listed in the Merck Index, the encyclopedia of chemicals, drugs, and biologicals, until 2001.

Lingering confusion over the difference between tocotrienols and tocopherols is understandable, considering that both have the same chromanol head. Today, alphatocopherol remains the most common vitamin E source on the market despite some lingering debate around it.

**Debate around Tocopherols**

Commercialization of natural, soy-derived tocopherols began in the 1950s; however, high demand for tocopherols prompted many companies to eventually switch from soy- and corn-derived tocopherols (whose crops typically yielded less than 20% alpha-tocopherol) to 100% alpha-tocopherol. Today, much of the “natural” alpha-tocopherol on the market is in fact semi-synthetic, with soy- and corn-based tocopherols synthesized to (RRR- or d-) alpha-tocopherol via the addition of one methyl group to gamma-tocopherol and two methyl groups to delta-tocopherol.

While synthetic tocopherol ingredients do exist in the market, synthetic tocotrienol ingredients do not. Tocotrienols are still sourced from a wide array of foods, including wheat, barley, and corn. Rice, palm, and annatto are the richest tocotrienol sources. Some research suggests that alpha-tocopherol interferes with the helpful activity of tocotrienols. Following an animal study...
published in the Journal of Nutrition in 1996\textsuperscript{14}, researchers suggested that tocotrienols were more potent hypocholesterolemic agents when administered with the lowest alpha-tocopherol content possible. In the study, chickens were fed either an alpha-tocopherol control diet or alpha-tocopherol administered in combination with gamma-tocotrienol. The group with the largest-supplemented amount of alpha-tocopherol showed increased activity of the rate-limiting enzyme responsible for cholesterol production, 3-hydroxy-3-methyl-glutaryl-CoA reductase (HMGR), and as a result cholesterol levels rose in that group—prompting researchers to conclude that in order for tocotrienols to help lower cholesterol, alpha-tocopherol content should not be more than 15%.

Four years later, another study in guinea pigs reported similar findings in favor of tocotrienols compared to tocopherols.\textsuperscript{15} In this study, researchers found that alpha-tocopherol, when co-administered with tocotrienols, reduced tocotrienols’ inhibitory effect on HMGR. When administered alone, tocotrienols reduced the enzyme’s activity by 48%; however, adding alpha-tocopherol meant that the combination inhibited HMGR by only 13%. Fast-forward through 15 years of clinical studies: tocopherol-tocotrienol mixtures did little or nothing to lower lipids, but when tocopherols were removed from the mixtures, lipids would decrease.\textsuperscript{16, 17}

Additional research suggests that tocopherols may be a monkey-wrench to tocotrienol functions. One small 2009 prospective study indicated that tocopherols may interfere with breast cancer medication\textsuperscript{18}, while a 2015 animal study\textsuperscript{19} found that excessive amounts of alpha-tocopherol may worsen stroke-related brain injuries. In 2005, those same researchers found that while orally supplemented alpha-tocotrienol was shown to reach most tissues and vital organs (including the skin, adipose tissue, ovaries, heart, liver, central nervous system, spinal cord, brain, lung, testes, and skeletal muscle), the mechanisms for transporting alpha-tocopherol and alpha-tocotrienol apparently compete, leading the researchers to note that “the transport efficiency of alpha-tocotrienol to tissues may be maximized by eliminating the co-presence of alpha-tocopherol in the oral supplement.”\textsuperscript{20}

The reasoning behind this can be readily understood. Of all eight isomers of vitamin E, only alpha-tocopherol has a known transport protein—a protein chaperone that provides a rite of passage—that recognizes alpha-tocopherol alone of all the eight isomers and delivers it to the tissues of interest. Then, by passive diffusion and emulsification with fats in a meal, all other vitamin E isomers get absorbed, like most lipid-soluble nutrients. Thus, co-supplementation with alpha-tocopherol is likely to compromise tissue delivery of alpha-tocotrienol.\textsuperscript{21} Alpha-tocopherol administration has also been

**Fibregum™**

All-natural soluble fiber

- Proven prebiotic benefits
- Exceptional digestive tolerance
- Gut barrier reinforcement*  
- Clean label & organic certified

**Fibregum™** products are all-natural, non-GMO, guaranteed minimum 90% soluble dietary fiber carefully selected and sourced from acacia gum trees. **Fibregum™** products appeal to consumers because they are clean label, 100% vegetable and available in certified organic grades. Several scientific studies have demonstrated the properties of acacia gum, including its prebiotic effect at a dose of 5-10 g/day and better intestinal transit regulation for a healthy digestive system.

A new study recently conducted by Nexira provided additional evidence showing Fibregum™ as a natural alternative to protect the intestinal barrier.

This statement has not been evaluated by the FDA.

This product is not intended to diagnose, treat, cure or prevent any disease.
Growing consumer demands for natural sources of vitamin E, coupled with promising research in several important health categories, should fuel more interest in tocotrienols.

Tocotrienols’ Time to Shine

While alpha-tocopherol research still occurs at a much greater level than tocotrienol research, there has been a downward trend in alpha-tocopherol research alongside an increase in understanding of tocotrienols driven by a growing body of science. Furthermore, FDA’s impending changes to the U.S. Nutrition Facts label, which include changing the unit of measure for vitamin E from IU to mg, will further underscore the differences between the two forms. Under the new labeling standard, 1 mg of natural vitamin E (RRR-alpha-tocopherol) equals 1 mg of vitamin E, but 2 mg of synthetic vitamin E (all-rac-alpha-tocopherol) equates to only 1 mg of natural vitamin E. The reason? In a nutshell: when synthesizing alpha-tocopherol, the stereochemistry changes that occur result in molecules that are not identical to natural alpha-tocopherol, although they may still be of the same molecular weight.

Growing consumer demands for natural sources of vitamin E, coupled with promising research in several important health categories, should fuel more interest in tocotrienols. Below are just a few study areas of interest showing positive results.

Editor’s note: Asterisks indicate studies performed by the author’s company, American River Nutrition (Hadley, MA), or on the company’s DeltaGold annatto tocotrienol ingredient. Some studies were also funded by American River Nutrition.

Cardiovascular Health

Thirty-one subjects with high cholesterol took escalating doses of tocotrienols—125, 250, 500, and 750 mg/day of American River Nutrition’s DeltaGold annatto tocotrienol—for four weeks each, with a two-week washout period between each dose. Researchers concluded that total cholesterol fell by 15%, while LDL cholesterol was reduced by 18%. Other notable outcomes: triglycerides decreased by 14%, and the cytokines associated with cardiovascular disease decreased by as much as 64%.*

Anti-Inflammation

The same parameters were employed to examine DeltaGold annatto tocotrienols’ effect on inflammatory markers, with equally impressive results. (Note: In this study and the one previously profiled, 250 mg/day was identified as an optimal dose of tocotrienols.) Among the promising results: C-reactive protein levels (a predictor of chronic inflammation) were reduced by 40%, and nitric oxide levels, which are aberrant in inflammatory conditions and should be reduced (only in inflammatory conditions), were also lowered by 40% in subjects.*

Two clinical studies indicate that delta-tocotrienol, combined with antioxidant polyphenols, may curb inflammation and help manage dyslipidemia (the elevation of plasma cholesterol), triglycerides, or both, or help to lower high-density lipoprotein levels that contribute to the development of atherosclerosis.* One placebo-controlled study was conducted in two groups of elderly subjects over six weeks, one with normal lipid levels, the other elevated. The product formulation was composed of DeltaGold delta-tocotrienol from annatto along with a B-vitamin (niacin) and polyphenols. In both groups, supplementation led to a significant drop in C-reactive protein and γ-glutamyltransferase (a predictor of non-fatal myocardial infarction and fatal coronary heart disease), while increasing total antioxidant status. In the hypercholesterolemic group, the following also dropped: LDL cholesterol (by 20%-28%) and triglycerides (by 11%-18%). C-reactive protein dropped in healthy elderly subjects (by 21%-29%) and in the hypercholesterolemic elderly (by 31%-48%). No adverse effects were observed.

Bone Health

In a 2017 in vivo study involving 48 female Sprague-Dawley rats, DeltaGold tocotrienol from annatto—with or without lovastatin—increased bone formation and mineralization in rats. Researchers concluded that “supplementation of tocotrienol in statin users can potentially protect them from osteoporosis.”

Our company is also embarking on (and sponsoring) a study of DeltaGold tocotrienols’ effect on the bone health of 89 postmenopausal women on tocopherol-free tocotrienol. This study will hopefully provide welcome clarity on how the nutrient affects human subjects. The study should be published in late 2017. As of this writing, early results look very promising.

Bioavailability

Tocotrienols’ bioavailability has been questioned in the past, resulting in the marketing of bio-enhanced, synthetic emulsions that are said to increase absorption. The solution for increasing tocotrienols’ bioavailability is easy, however, and time-tested: take tocotrienols with a meal.

Two studies on DeltaGold confirmed the bioavailability of tocopherol-free annatto tocotrienol. An open-label randomized trial involved 125, 250, 500, 750, and 1000 mg/day dosage groups. Many pharmacokinetic parameters were studied in healthy subjects to ascertain that delta- and gamma-tocotrienol were absorbed. When taken with a meal, both tocotrienols were absorbed and bioavailable.*

The Future for Tocotrienols

Research clearly shows that not all vitamin E isomers are the same. Tocotrienols

found to decrease the gamma-tocotrienol concentration in the adipose tissue and skin, inhibiting both alpha-tocotrienol and gamma-tocotrienol tissue uptake.*

When taken with a meal, both tocotrienols were absorbed and bioavailable.*

The Future for Tocotrienols

Research clearly shows that not all vitamin E isomers are the same. Tocotrienols
have well-differentiated functions from tocopherols, with a growing body of evidence supporting its benefits for chronic conditions. Considering that studies show that tocopherol does not augment the function of tocotrienol, but rather antagonizes it, in my professional opinion, in order to fully appreciate the benefits of tocotrienol, manufacturers should formulate with delta- and gamma-tocotrienols, without tocopherol or with the lowest amount of alpha-tocopherol possible.

Barrie Tan, PhD, a foremost vitamin E expert, is credited with identifying the primary sources of plant-based tocotrienols. Today, his research focuses on nutrients that impact aging conditions. Tan is the senior editor of Tocotrienols: Vitamin E Beyond Tocopherols (2013), and collaborates with universities worldwide to further tocotrienol research.
